

Consecutive Repeating State Cycles Determine Periodic Points in a Turing Machine

Michael Stephen Fiske

Abstract The Turing machine is studied with new methods motivated by the notion of recurrence in classical dynamical systems theory. The state cycle of a Turing machine is introduced. It is proven that each consecutive repeating state cycle in a Turing machine determines a unique periodic configuration (point) and vice versa. This characterization is a *periodic point* theorem for Turing machines. A Turing machine is defined to be periodic if it has at least one periodic configuration or it only has halting configurations. Using the notion of a prime directed edge and a mathematical operation called edge pattern substitution, a search procedure finds consecutive repeating state cycles. If the Turing machine is periodic, then this procedure eventually finds each periodic point or this procedure determines that the machine has only halting configurations. New mathematical techniques are demonstrated - such as edge pattern substitution and prime directed edge sequences - that could be quite useful in the further study of the aperiodic Turing machines. The aperiodicity appears to play an integral role in the undecidability of the Halting problem.

1 Introduction

New results are achieved here by analyzing the Turing machine from a dynamical systems point of view. Classical dynamical systems theory has been successful by first understanding the periodic behavior and then studying more general recurrent behavior (as in [3], [4], [7], and [11]). This paper follows the classical approach, by finding a notion of recurrence that characterizes periodic configurations of a Turing machine.

In the next section, the Turing machine is briefly reviewed and then some definitions are presented for studying its recurrent behavior. The Turing machine is represented as (Q, A, η) where Q is a finite set of states, A is a finite alphabet and

Michael Stephen Fiske

the program η is a function $\eta : Q \times A \rightarrow Q \times A \times \{-1, +1\} \cup \{\mathcal{H}\} \times A \times \{0\}$. A Turing machine configuration (q, k, T) is a triplet, where q is the current state of the machine, the function $T : Z \rightarrow A$ represents the tape, where Z is the integers and k is an integer that is the tape head location. A machine starts program execution at configuration (q, k, T) where $T(k) = \alpha$ and η determines the next configuration according to three cases:

1. $(r, k-1, S)$ if $\eta(q, \alpha) = (r, \beta, -1)$
2. $(r, k+1, S)$ if $\eta(q, \alpha) = (r, \beta, +1)$
3. (\mathcal{H}, k, S) if $\eta(q, \alpha) = (\mathcal{H}, \beta, 0)$

such that for all three cases the new tape $S(j) = T(j)$ whenever $j \neq k$ and $S(k) = \beta$.

Case 1 means that the machine moves to state r , replaces alphabet symbol α with symbol β at tape square k and then moves the tape head left -1 to tape square $k-1$. Case 2 means the same as Case 1 except the tape head moves right $+1$ to tape square $k+1$. Case 3 means that the machine reaches a unique halting state \mathcal{H} and the program execution halts.

A configuration (q, k, T) is called a halting configuration if machine execution starts at (q, k, T) , and after a finite number of execution steps, the machine reaches the halting state. A configuration (q, k, T) is periodic if after the execution of n computational steps of the Turing machine, the new configuration (r, j, S) has the same state and the same tape contents. This means $r = q$ and the same tape contents means $T(x+k) = S(x+j)$ for every integer x . In this case, (q, k, T) is a periodic configuration. Thus, all periodic configurations are immortal. A Turing machine is called *periodic* if it has at least one periodic configuration or it only has halting configurations.

The state cycle is a notion of recurrence for the Turing machine. A state cycle is a non-halting execution sequence of input commands $(q_0, a_0) \rightarrow (q_1, a_1) \rightarrow \dots \rightarrow (q_{N-1}, a_{N-1}) \rightarrow (q_N, a_N)$, such that $q_0 = q_N$ and where pair (q, α) in $\eta(q, \alpha)$ is called an input command. A state cycle is called a prime state cycle if it contains no proper state subcycles. A consecutive repeating state cycle is a state cycle that repeats itself twice, where the second repeat immediately follows the first: $(q_0, a_0) \rightarrow (q_1, a_1) \rightarrow \dots \rightarrow (q_{N-1}, a_{N-1}) \rightarrow (q_0, a_0) \rightarrow (q_1, a_1) \rightarrow \dots \rightarrow (q_{N-1}, a_{N-1})$.

At the end of the second section, a *periodic point theorem that holds for any Turing machine* is proved: a consecutive repeating state cycle uniquely determines a periodic configuration of the Turing machine and also vice versa that a periodic configuration uniquely determines a consecutive repeating state cycle. Thus, to search for a periodic configuration, a procedure may look for consecutive repeating state cycles.

In the third section, the prime directed edge is defined. The prime directed edge represents, over a window of execution, a Turing machine program visiting only one state twice and visiting the other states one time or not at all. Thus, a prime directed edge contains a prime state cycle. Pattern matching determines how two prime directed edges are glued together. When prime directed edges are glued together, this

is called link matching. The link matching is used to build prime directed edge sequences. Based on $|Q|$ and $|A|$, an upper bound on the number of prime directed edges is computed. The prime directed edge sequences cover all Turing program execution possibilities. As a consequence, the number of prime directed edges is a useful measure of the Turing machine complexity. For a given Turing machine, a procedure for finding all prime directed edges is shown. After this, a periodic point search procedure is described whereby prime directed edges are link matched together to form prime directed edge sequences. This procedure searches for consecutive repeating state cycles inside the edge sequences.

In [9], Kurka conjectured that any Turing machine that has no halting configurations has a periodic configuration. In [2], Blondel et al demonstrated that some Turing machines have only aperiodic immortal configurations. Furthermore, Blondel et al. showed in [2] that determining whether a given counter machine has a periodic orbit in configuration space is undecidable.

In this context, there are two main results. First, that each consecutive repeating state cycle determines a unique periodic point in a Turing Machine and vice versa. Second, using this first result, if a Turing machine is periodic, then the search procedure can determine whether the machine only has halting configurations or, if not, then this procedure finds a periodic configuration of this machine. Furthermore, the procedure demonstrated can be used to find periodic configurations of any length when they exist. Finally, the mathematical tools developed here – e.g. the prime directed edge, the edge substitution operator, link matching, and prime directed edge sequences – can be used to study the aperiodic immortal configurations, which could help better understand the dynamics of the Halting problem [12].

2 Turing Machines & Periodic Configurations

The Turing Machine is defined here so that its program η is explicitly represented as a function.

Definition 1. *Turing Machine*

A Turing machine is a triple (Q, A, η) where

1. Q is a finite set of states that does not contain a unique halt state \mathcal{H} .
2. The machine execution starts in an initial state s and s lies in Q .
3. A is a finite set of alphabet symbols that are read from and written to the tape.
4. -1 and $+1$ represent advancing the tape head to the left or right square, respectively.
5. $\eta : Q \times A \rightarrow Q \times A \times \{-1, +1\} \cup \{\mathcal{H}\} \times A \times \{0\}$ is a function. η acts as the program for the Turing machine. For each q in Q and α in A , $\eta(q, \alpha) = (r, \beta, x)$ describes how machine (Q, A, η) executes one computational step. When in state q and scanning alphabet symbol α on the tape:

- a. Machine (Q, A, η) changes to state r .
- b. Machine (Q, A, η) rewrites alphabet symbol α as symbol β on the tape.
- c. If $x = -1$, then machine (Q, A, η) moves its tape head one square to the left on the tape and is subsequently scanning the symbol in this square.
- d. If $x = +1$, then machine (Q, A, η) moves its tape head one square to the right on the tape and is subsequently scanning the symbol in this square.
- e. If $r = \mathcal{H}$, machine (Q, A, η) reaches halting state \mathcal{H} and halts.

Definition 2. *Turing Machine tape*

The Turing machine tape T is represented as a function $T : Z \rightarrow A$ where Z denotes the integers. The tape T is M -bounded if there exists a bound $M > 0$ such that $T(k) = T(j)$ whenever $|k|, |j| \geq M$.

The Turing machine definitions in [5], [12] assume the initial tape, before program execution begins, is M -bounded and the tape contains only blank symbols, denoted here as #, outside the bound. In this paper, the tape is not assumed to be M -bounded, unless this is explicitly stated for a particular case. The symbol on the k th square of the tape is $T(k)$.

Definition 3. *Turing Machine Configuration with tape head location*

Let (Q, A, η) be a Turing machine with tape T . A configuration is an element of the set $C = (Q \cup \{\mathcal{H}\}) \times Z \times \{T : T \text{ is tape with range } A\}$. If (q, k, T) is a configuration, then k is called the tape head location.

Consider the configuration $(p, 2, \dots \#\#\alpha\beta\#\#\dots)$. The 1st coordinate indicates that the Turing machine is in state p . The 2nd coordinate indicates that its tape head is currently scanning tape square 2, denoted as $T(2)$. The 3rd coordinate indicates that tape square 1 contains symbol α , tape square 2 contains symbol β , and all other tape squares contain the # symbol. Sometimes a periodic configuration $p = (q, k, T)$ is called a periodic point or immortal periodic point.

Definition 4. *Computational Period and Hyperbolic Degree*

Consider immortal periodic point p . If the machine starts its execution at point p , then the minimal number of computational steps, denoted $C(p)$, for the machine to return to point p is called the computational period of p . Observe that $C(p) = R + L$ where R and L denote the number of right and left tape head moves respectively. Define the hyperbolic degree of p as $m(p) = R - L$. If $m \neq 0$, the periodic point is called *hyperbolic*. Otherwise, p is called non-hyperbolic.

The computational period is motivated by the classical dynamical systems definition of the period of a point p in X for an autonomous (e.g. [6]) dynamical system $f : X \rightarrow X$ where X is a topological space, f is a function and m is the minimal positive integer such that $f^m(p) = p$. The hyperbolic degree is analogous to the classical dynamical systems definition of a hyperbolic periodic point of $f : X \rightarrow X$ when X is a manifold and f is differentiable.

A *pattern* W is a finite sequence of alphabet symbols chosen from A . In other words, $W : \{0, 1, \dots, n-1\} \rightarrow A$. The length of $W = n$ and is denoted as $|W| =$

n . The k th element of the pattern W is denoted as $W(k)$ or w_k . Thus, pattern W is sometimes explicitly expressed as $w_0w_1 \dots w_{n-1}$. S is a *subpattern* of W if $S = w_jw_{j+1} \dots w_{k-1}w_k$ for some j and k satisfying $0 \leq j \leq k \leq n-1$ and the length of $S = k - j + 1$. A pattern represents a finite sequence of the tape.

The expression $[4, \underline{121212}]$ represents the point p where the machine is in state 4; the tape head is located at the underlined 1; the tape to the right of the tape head contains the periodic pattern 212 212 \dots ; and the tape to the left of the tape head contains the periodic pattern $\dots 12 12 12$.

Example 1. Non-Hyperbolic Periodic Point

The state set is $Q = \{q, r\}$ and the alphabet set is $A = \{1, 2\}$. The halting state is \mathcal{H} . η is defined below.

$$\begin{aligned} \eta(q, 1) &= (\mathcal{H}, 1, 0) & \eta(q, 2) &= (r, 2, -1) \\ \eta(r, 1) &= (q, 2, +1) & \eta(r, 2) &= (q, 1, +1) \end{aligned}$$

Consider program execution steps: $[r, x\underline{22}y] \mapsto [q, x1\underline{2}y] \mapsto [r, x1\underline{2}y] \mapsto [q, x\underline{22}y] \mapsto [r, x\underline{22}y]$, where x is any infinite left tape sequence chosen from A and y is any infinite right tape sequence. The tape head moves for this non-hyperbolic immortal periodic point are $[+1, -1, +1, -1]$. All points of the form $p = [r, x\underline{22}y]$ are non-hyperbolic periodic points with period 4.

Example 2. Hyperbolic Periodic Point

The state set is $Q = \{q, r, s, t, u, v, w, x\}$ and the alphabet set is $A = \{1, 2\}$. η is defined below.

$$\begin{aligned} \eta(q, 1) &= (r, 1, +1) & \eta(q, 2) &= (\mathcal{H}, 2, 0) \\ \eta(r, 1) &= (\mathcal{H}, 1, 0) & \eta(r, 2) &= (s, 2, +1) \\ \eta(s, 1) &= (t, 1, +1) & \eta(s, 2) &= (\mathcal{H}, 2, 0) \\ \eta(t, 1) &= (\mathcal{H}, 1, 0) & \eta(t, 2) &= (u, 2, +1) \\ \eta(u, 1) &= (\mathcal{H}, 1, 0) & \eta(u, 2) &= (v, 1, +1) \\ \eta(v, 1) &= (\mathcal{H}, 1, 0) & \eta(v, 2) &= (w, 2, +1) \\ \eta(w, 1) &= (\mathcal{H}, 1, 0) & \eta(w, 2) &= (x, 1, -1) \\ \eta(x, 1) &= (\mathcal{H}, 1, 0) & \eta(x, 2) &= (q, 2, +1) \end{aligned}$$

The point $p = [q, \underline{12} \underline{1} \overline{212222}]$ is an immortal periodic point with computational period 8 and hyperbolic degree 6.

Definition 5. *Window of Execution*

Consider the next N computational steps of a Turing machine. The window of execution, denoted as $[\ell, \mu]$ or $[\ell, \ell + 1, \dots, \mu]$, is the sequence of integers representing the tape squares that the tape head visited during these N computational steps. The length of the window of execution is $\mu - \ell + 1$ which is also the number of distinct tape squares visited by the tape head during these N steps. To express the window of execution for the next n computational steps, the lower and upper bounds are expressed as a function of n : $[\ell(n), \mu(n)]$. If $j \leq k$, then $[\ell(j), \mu(j)] \subseteq [\ell(k), \mu(k)]$ which follows from the definition.

The purpose of the window of execution is to describe only the portion of the tape that the tape head visits during the next N computational steps. This is useful because all tape squares outside the window of execution remain unchanged during those N steps. Since the tape squares may be renumbered without changing the results of the machine execution, for convenience it is often assumed that the machine starts execution at tape square 0. In example 2, during the next 8 computational steps – that is, one cycle of the immortal periodic point – the window of execution is $[0, 6]$ and its length is 7.

3 State Cycles

This section introduces state cycles and consecutive repeating state cycles. Subsequently, a proof shows that a consecutive repeating state cycle uniquely determines a periodic point and a periodic point determines a unique consecutive repeating state cycle.

Definition 6. *State Cycle*

Consider N execution steps of Turing Machine (Q, A, η) . After each execution step, the machine is in some state q_k and the tape head is pointing to some alphabet symbol a_k . Relabel the indices of the states and the alphabet symbols if necessary and assume the machine has not halted after N execution steps. This execution sequence of input commands is $(q_0, a_0) \mapsto (q_1, a_1) \mapsto \dots \mapsto (q_{N-1}, a_{N-1}) \mapsto (q_N, a_N)$, where each pair (q_k, a_k) executed as $\eta(q_k, a_k)$ is called an input command. A *state cycle* is a non-halting execution sequence of input commands such that the first and last input command in the sequence have the same state: $(q_k, a_k) \mapsto (q_{k+1}, a_{k+1}) \mapsto \dots \mapsto (q_{N-1}, a_{N-1}) \mapsto (q_k, a_k)$. The length of this state cycle equals the number of input commands minus one. A state cycle is called a *prime state cycle* if it contains no proper state subcycles. For a prime state cycle, the length of the cycle equals the number of distinct states in the sequence. For example, $(2, 0) \mapsto (3, 1) \mapsto (4, 0) \mapsto (2, 1)$ is called a prime 3-state cycle because it has length 3 and also 3 distinct states $\{2, 3, 4\}$.

Remark 1. Any prime state cycle has length $\leq |Q|$

Proof. This follows from the pigeonhole principle and the definition of a prime state cycle.

Remark 2. Any state cycle contains a prime state cycle

Proof. Relabeling if necessary let $\zeta(q_1, q_1) = (q_1, a_1) \mapsto \dots \mapsto (q_n, a_n) \mapsto (q_1, a_{n+1})$ be a state cycle. If q_1 is the only state visited twice, then the proof is completed. Otherwise, define $\ell = \min\{|\zeta(q_k, q_k)| : \zeta(q_k, q_k) \text{ is a subcycle of } \zeta(q_1, q_1)\}$. Then ℓ exists because $\zeta(q_1, q_1)$ is a subcycle of $\zeta(q_1, q_1)$. Claim: Any state cycle $\zeta(q_j, q_j)$ with $|\zeta(q_j, q_j)| = \ell$ must be a prime state cycle. Suppose not. Then there is a state $r \neq q_j$ that is visited twice in the state cycle $\zeta(q_j, q_j)$. But then $\zeta(q_r, q_r)$ is a cycle with length less than ℓ which contradicts ℓ 's definition.

Definition 7. *Consecutive repeating state cycle*

If machine (Q, A, η) during program execution repeats a state cycle two consecutive times, $(q_1, b_1) \mapsto \dots \mapsto (q_n, b_n) \mapsto (q_1, b_1) \mapsto \dots \mapsto (q_n, b_n) \mapsto (q_1, b_1)$, then (Q, A, η) has a consecutive repeating state cycle.

Theorem 1. *Each periodic point determines a unique consecutive repeating state cycle*

Proof. Suppose p is an immortal periodic point with period n . Let the input command sequence $(q_1, b_1) \mapsto \dots \mapsto (q_n, b_n) \mapsto (q_{n+1}, b_{n+1})$ denote the first n input commands that are executed. Since p has period n , $(q_1, b_1) = (q_{n+1}, b_{n+1})$. Thus, the first n steps are a state cycle $(q_1, b_1) \mapsto \dots \mapsto (q_n, b_n) \mapsto (q_1, b_1)$. Since the $n+1$ computational step corresponds to applying η to p , the window of execution is identical for the next n steps as it was for the first n steps. Thus, the next n steps have an input command sequence that is identical as the first n steps. Thus, the sequence of input commands for $2n$ steps is $(q_1, b_1) \mapsto \dots \mapsto (q_n, b_n) \mapsto (q_1, b_1) \mapsto \dots \mapsto (q_n, b_n) \mapsto (q_1, b_1)$.

Theorem 2. *Each consecutive repeating state cycle determines a unique periodic point*

Proof. The proof is in Nonlinear Dynamics and Synchronization 2012, available at www.springerlink.com.

4 Prime Directed Edge Sequences

Edge pattern substitution is the mathematical operation used to link match prime directed edges. Prime directed edges are link matched to construct prime directed edge sequences. The notion of an overlap match expresses how a part or all of one tape pattern may match part or all of another tape pattern.

Definition 8. *Overlap Matching & Intersection Patterns*

Let V and W be patterns. (V, s) overlap matches (W, t) if and only if $V(s+c) = W(t+c)$ for each integer c satisfying $-\ell \leq c \leq \mu$ such that $\ell = \min\{s, t\}$ and $\mu = \min\{|V| - 1 - s, |W| - 1 - t\}$ where $0 \leq s < |V|$ and $0 \leq t < |W|$. The index s is called the head of pattern V and the index t is called the head of pattern W . If V is also a subpattern, then (V, s) submatches (W, t) . If (V, s) overlap matches (W, t) , then define the intersection pattern I with head $u = \ell$ as $(I, u) = (V, s) \cap (W, t)$, where $I(c) = V(c+s-\ell)$ for every integer c satisfying $0 \leq c \leq (\ell + \mu)$ where $\ell = \min\{s, t\}$ and $\mu = \min\{|V| - 1 - s, |W| - 1 - t\}$.

Definition 9. *Edge Pattern Substitution Operator*

Given patterns $V = v_0v_1 \dots v_n$ and $W = w_0w_1 \dots w_n$ with heads s, t satisfying $0 \leq s, t \leq n$ and pattern $P = p_0p_1 \dots p_m$ with head u satisfying $0 \leq u \leq m$. If (P, u)

overlap matches (V, s) , define the edge pattern substitution operator \oplus as $E = (P, u) \oplus [(V, s) \Rightarrow (W, t)]$ according to the four different cases **A**, **B**, **C** and **D**.

Case A $u > s$ and $m - u > n - s$

$$E(k) = \begin{cases} W(k+s-u) & \text{if } u-s \leq k \leq u+n-s \\ P(k) & \text{if } 0 \leq k < u-s \text{ or } u+n-s < k \leq m \end{cases}$$

The head of E is $u+t-s$ and $|E| = m+1$.

$$\begin{array}{cccccccc} p_0 & p_1 & \dots & p_{u-s} & \dots & \underline{p_u} & \dots & p_{u+n-s} & \dots & p_m \\ v_0 & & & & & \underline{v_s} & & & & v_n \\ w_0 & & & & & \underline{w_s} & & & & w_n \end{array}$$

Case B $u > s$ and $m - u \leq n - s$

$$E(k) = \begin{cases} W(k+s-u) & \text{if } u-s \leq k \leq n+u-s \\ P(k) & \text{if } 0 \leq k < u-s \end{cases}$$

The head of E is $u+t-s$ and $|E| = n+u-s+1$.

$$\begin{array}{cccccccc} p_0 & p_1 & \dots & p_{u-s} & \dots & \underline{p_u} & \dots & p_m \\ v_0 & & & & & \underline{v_s} & & v_{s+m-u} & \dots & v_n \\ w_0 & & & & & \underline{w_s} & & w_{s+m-u} & \dots & w_n \end{array}$$

Case C $u \leq s$ and $m - u \leq n - s$

$E(k) = W(k)$ when $0 \leq k \leq n$. The head of E is t and $|E| = |W| = n+1$.

$$\begin{array}{cccccccc} p_0 & & & \dots & \underline{p_u} & \dots & p_m \\ v_0 & \dots & v_{s-u} & \dots & \underline{v_s} & \dots & v_{s+m-u} & \dots & v_n \\ w_0 & \dots & w_{s-u} & \dots & \underline{w_s} & \dots & w_{s+m-u} & \dots & w_n \end{array}$$

Case D $u \leq s$ and $m - u > n - s$

$$E(k) = \begin{cases} P(k+u-s) & \text{if } n < k \leq m+s-u \\ W(k) & \text{if } 0 \leq k \leq n \end{cases}$$

The head of E is t and $|E| = m+s-u+1$.

$$\begin{array}{cccccccc} p_0 & & & \dots & \underline{p_u} & \dots & p_{u+n-s} & \dots & p_m \\ v_0 & \dots & v_{s-u} & \dots & \underline{v_s} & \dots & v_n \\ w_0 & \dots & w_{s-u} & \dots & \underline{w_s} & \dots & w_n \end{array}$$

Set pattern $P = 0101\ 110$. Set pattern $V = 11\ \underline{0}101$. Set pattern $W = 01\ 00\underline{1}0$. Then $(P, 0)$ overlap matches $(V, 2)$. Thus, the edge pattern substitution operation is well-defined so $E = (P, 0) \oplus [(V, 2) \Rightarrow (W, 4)] = 01\ 00\underline{1}0\ 110$. The head or index of pattern $E = 4$. Furthermore, $(P, 4)$ overlap matches $(V, 0)$. Thus, $F = (P, 4) \oplus [(V, 0) \Rightarrow (W, 4)] = 0101\ 0100\underline{1}0$. The index of pattern $F = u+t-s = 4+4-0 = 8$.

Definition 10. Execution node for (Q, A, η)

An execution node is a triplet $\mathfrak{N} = [q, w_0w_1 \dots w_n, t]$ for some state q in Q where $w_0w_1 \dots w_n$ is a pattern of $n+1$ alphabet symbols each in A such that t is a non-negative integer satisfying $0 \leq t \leq n$. Intuitively, $w_0w_1 \dots w_n$ is the pattern of alphabet symbols on $n+1$ consecutive tape squares on the tape and t represents the location of the tape head.

Definition 11. *Halting Execution Node*

Suppose $[q, v_0v_1 \dots v_n, s]$ is an execution node and over the next $|Q|$ computational steps a prime state cycle is not found. In other words, a prime directed edge is not generated. Then the Turing machine execution halted in $|Q|$ or less steps. Let W be a pattern such that (W, t) submatches (V, s) and W spans the window of execution until execution halts. Define the halting node as $H = [q, W, t]$.

Definition 12. *Prime directed edge*

A prime head execution node $\mathfrak{H} = [q, v_0v_1 \dots v_n, s]$ and prime tail execution node $\mathfrak{T} = [r, w_0w_1 \dots w_n, t]$ are called a prime directed edge iff all of the following hold:

1. When Turing machine (Q, A, η) starts execution, it is in state q ; the tape head is located at tape square s . For each j satisfying $0 \leq j \leq n$ tape square j contains symbol v_j . In other words, the initial tape pattern is $v_0v_1 \dots v_s \dots v_n$.
2. During the next N computational steps, state r is visited twice and all other states in Q are visited at most once. In other words, the corresponding sequence of input commands during the N computational steps executed contains only one prime state cycle.
3. After N computational steps, where $1 \leq N \leq |Q|$, the machine is in state r . The tape head is located at tape square t . For each j satisfying $0 \leq j \leq n$ tape square j contains symbol w_j . The tape pattern after the N computational steps is $w_0w_1 \dots w_t \dots w_n$.
4. The window of execution for these N computational steps is $[0, n]$.

A prime directed edge is denoted as $[q, v_0v_1 \dots v_n, s] \Rightarrow [r, w_0w_1 \dots w_n, t]$ or $\mathfrak{H} \Rightarrow \mathfrak{T}$. The number of computational steps N is denoted as $|\mathfrak{H} \Rightarrow \mathfrak{T}|$.

Definition 13. *Overlap matching of a node to a prime head node*

Execution node \mathfrak{N} overlap matches head execution node \mathfrak{H} iff the following hold:

1. $\mathfrak{N} = [r, w_0w_1 \dots w_n, t]$ is an execution node satisfying $0 \leq t \leq n$.
2. $\mathfrak{H} = [q, v_0v_1 \dots v_m, s]$ is a prime head node satisfying $0 \leq s \leq m$.
3. State $q =$ State r .
4. Pattern (W, t) overlap matches (V, s) , where $W = w_0w_1 \dots w_n$ and $V = v_0v_1 \dots v_m$.

Lemma 1. *Overlap matching prime head nodes are equal*

If $\mathfrak{H}_j = [q, P, u]$ and $\mathfrak{H}_k = [q, V, s]$ are prime head nodes and they overlap match, then they are equal. Distinct prime directed edges have prime head nodes that do not overlap match.

Proof. From the definition of prime edge, $0 \leq u \leq |P|$ and $0 \leq s \leq |V|$. Let $(I, m) = (P, u) \cap (V, s)$ where $m = \min\{s, u\}$. Suppose the same machine begins execution on tape I with tape head at m in state q . If $s = u$ and $|P| = |V|$, then the proof is complete. Otherwise, $s \neq u$ or $|P| \neq |V|$ or both. \mathfrak{H}_j has a window of execution

$[0, |P| - 1]$ and \mathfrak{H}_k has window of execution $[0, |V| - 1]$. Let the i th step be the first time that the tape head exits finite tape I . This means the machine would execute the same machine instructions with respect to \mathfrak{H}_j and \mathfrak{H}_k up to the i th step, so on the i th step, \mathfrak{H}_j and \mathfrak{H}_k must execute the same instruction. Since it exits tape I at the i th step, this would imply that either pattern P or V are exited at the i th step. This contradicts either that $[0, |P| - 1]$ is the window of execution for \mathfrak{H}_j or $[0, |V| - 1]$ is the window of execution for \mathfrak{H}_k .

Theorem 3. *The number of prime directed edges is $\leq |Q|^2 |A|^{|Q|+1}$*

Proof. From 1, each prime head node determines a unique prime directed edge so an upper bound for head nodes provides an upper bound for the prime directed edges. Consider prime head node $[q, V, s]$. There are $|Q|$ choices for the state q . Any pattern that represents the window of execution has length $\leq |Q| + 1$. Furthermore, 1 implies, for any pattern P that (V, s) submatches (P, t) , then the resultant pattern is the same since V spans the window of execution. Thus, $|A|^{|Q|+1}$ is an upper bound for the number of different patterns V . Lastly, there are two choices for s in a $|Q| + 1$ length pattern because the maximum number of execution steps is $|Q|$ (i.e., the tape head move sequence is either $|Q|$ consecutive left tape head moves or $|Q|$ right tape head moves). Thus, $|Q|$ is an upper bound for the number of choices for s unless $|Q| = 1$. The bound holds in the trivial case that $|Q| = 1$. Thus, there are at most $|Q|^2 |A|^{|Q|+1}$ prime directed edges.

$|Q|^2 |A|^{|Q|+1}$ is not a strict upper bound. Procedure 2 describes an algorithm for finding all the prime directed edges of a Turing machine, which also provides the number of prime directed edges.

Definition 14. *Edge Node Substitution Operator*

Let $\mathfrak{H} \Rightarrow \mathfrak{T}$ be a prime directed edge with prime head node $\mathfrak{H} = [q, v_0 v_1 \dots v_n, s]$ and tail node $\mathfrak{T} = [r, w_0 w_1 \dots w_n, t]$. If execution node $\mathfrak{N} = [q, p_0 p_1 \dots p_m, u]$ overlap matches \mathfrak{H} , then the edge pattern substitution operator in definition 9 induces a new execution node $\mathfrak{N} \oplus (\mathfrak{H} \Rightarrow \mathfrak{T}) = [r, (P, u) \oplus [(V, s) \Rightarrow (W, t)], k]$ with head $k = u + t - s$ if $u > s$ and head $k = t$ if $u \leq s$ such that $0 \leq s, t \leq n$ and $0 \leq u \leq m$ and patterns $V = v_0 v_1 \dots v_n$ and $W = w_0 w_1 \dots w_n$ and $P = p_0 p_1 \dots p_m$.

Let $\mathfrak{P} = \{\mathfrak{H}_1 \Rightarrow \mathfrak{T}_1, \dots, \mathfrak{H}_k \Rightarrow \mathfrak{T}_k, \dots, \mathfrak{H}_N \Rightarrow \mathfrak{T}_N\}$ denote the finite set of prime directed edges for (Q, A, η) . The number of prime directed edges in \mathfrak{P} is $|\mathfrak{P}|$ and is called the *prime directed edge (PE) complexity* of (Q, A, η) . As defined in 14, the link matching step compares two tape patterns, one from execution node \mathfrak{N}_k and the other from head node \mathfrak{H}_{k+1} . If the tape patterns overlap match and the state of \mathfrak{N}_k equals the state of \mathfrak{H}_{k+1} , then the edge node substitution operation is well-defined and is used to glue prime directed edge $\mathfrak{H}_{k+1} \Rightarrow \mathfrak{T}_{k+1}$ to execution node \mathfrak{N}_k . In other words, $\mathfrak{N}_{k+1} = \mathfrak{N}_k \oplus (\mathfrak{H}_{k+1} \Rightarrow \mathfrak{T}_{k+1})$ is computed.

Definition 15. *Prime directed edge sequence and Link Matching*

A prime directed edge sequence is defined inductively. Each element is a coordinate pair, where the first element is a prime directed edge, the second element is an

execution node and each element is expressed as $(\mathfrak{H}_k \Rightarrow \mathfrak{T}_k, \mathfrak{N}_k)$. The first element of a prime directed edge sequence is $(\mathfrak{H}_1 \Rightarrow \mathfrak{T}_1, \mathfrak{N}_1)$ where $\mathfrak{N}_1 = \mathfrak{T}_1$, and $\mathfrak{H}_1 \Rightarrow \mathfrak{T}_1$ is some prime directed edge in \mathfrak{P} . For simplicity in this definition, the indices in \mathfrak{P} are relabeled if necessary so the first element has indices equal to 1. If \mathfrak{N}_1 overlap matches some non-halting prime head node \mathfrak{H}_2 , the second element of the prime directed edge sequence is $(\mathfrak{H}_2 \Rightarrow \mathfrak{T}_2, \mathfrak{N}_2)$ where $\mathfrak{N}_2 = \mathfrak{N}_1 \oplus (\mathfrak{H}_2 \Rightarrow \mathfrak{T}_2)$. This is called a link match step. Otherwise, \mathfrak{N}_1 overlap matches a halting node, as defined in 11. In this case, the prime directed edge sequence terminates and this is called a halting match step. This is expressed as $[(\mathfrak{H}_1 \Rightarrow \mathfrak{T}_1, \mathfrak{T}_1), \mathcal{H}]$.

If the first $k-1$ steps are link match steps, then the edge sequence up to the k th element is inductively defined as $[(\mathfrak{H}_1 \Rightarrow \mathfrak{T}_1, \mathfrak{N}_1), (\mathfrak{H}_2 \Rightarrow \mathfrak{T}_2, \mathfrak{N}_2), \dots, (\mathfrak{H}_k \Rightarrow \mathfrak{T}_k, \mathfrak{N}_k)]$ where \mathfrak{N}_j overlap matches prime head node \mathfrak{H}_{j+1} and $\mathfrak{N}_{j+1} = \mathfrak{N}_j \oplus (\mathfrak{H}_{j+1} \Rightarrow \mathfrak{T}_{j+1})$ for each j satisfying $0 \leq j < k$.

5 Search Procedure for Periodic Points

This section demonstrates how to search for any periodic point – when they exist – by looking for consecutive repeating state cycles inside a prime directed edge sequence. This procedure is useful because it does not search over a tape pattern that has already been previously examined. This is due to Lemma 1 that proves if two head nodes overlap match in their respective prime directed edges, then the prime directed edges are equal.

Although there are other methods to look for periodic points, this search procedure demonstrates a broader approach because each aperiodic immortal configuration corresponds to a unique prime directed edge sequence. This is relevant because the non-trivial recurrence of the M -bounded aperiodic immortal configurations is integral to the undecidability of the Halting problem.

Link matching is a computational operation used to construct prime directed edge sequences. The following example link matches two prime directed edges.

Example 3. Link matching prime directed edges

State set $Q = \{q, r, s, t, u\}$. Alphabet set $A = \{0, 1\}$. Program η is defined below.

$$\begin{array}{ll} \eta(q, 0) = (r, 1, +1) & \eta(q, 1) = (r, 1, -1) \\ \eta(r, 0) = (\mathcal{H}, 1, 0) & \eta(r, 1) = (s, 0, +1) \\ \eta(s, 0) = (t, 0, +1) & \eta(s, 1) = (\mathcal{H}, 1, 0) \\ \eta(t, 0) = (u, 1, -1) & \eta(t, 1) = (q, 0, +1) \\ \eta(u, 0) = (q, 1, -1) & \eta(u, 1) = (t, 0, +1) \end{array}$$

The execution steps of $[u, 00010, 1] \Rightarrow [q, 10000, 4]$ are shown in table 1.

The execution steps of $[q, 01010, 0] \Rightarrow [q, 10000, 4]$ are shown in table 2.

Prime edge $[u, 00010, 1] \Rightarrow [q, 10000, 4]$ can be link matched to prime edge $[q, 01010, 0] \Rightarrow [q, 10000, 4]$. After link matching, the sequence of input commands is $[(u, 0), (q, 0), (r, 1), (s, 0), (t, 1), (q, 0), (r, 1), (s, 0), (t, 1)]$. Observe that $[(q, 0), (r, 1),$

r	<u>11010</u>	1	$\eta(r, 1) = (s, 0, +1)$
s	<u>10010</u>	2	$\eta(s, 0) = (t, 0, +1)$
t	<u>10010</u>	3	$\eta(t, 1) = (q, 0, +1)$
q	<u>10000</u>	4	

Table 2 Prime Directed Edge $[q, \underline{01010}, 0] \Rightarrow [q, \underline{10000}, 4]$

STATE	TAPE	HEAD	COMMAND
q	<u>01010</u>	0	$\eta(q, 0) = (r, 1, +1)$
r	<u>11010</u>	1	$\eta(r, 1) = (s, 0, +1)$
s	<u>10010</u>	2	$\eta(s, 0) = (t, 0, +1)$
t	<u>10010</u>	3	$\eta(t, 1) = (q, 0, +1)$
q	<u>10000</u>	4	

$(s, 0), (t, 1), (q, 0), (r, 1), (s, 0), (t, 1)$ is a consecutive repeating state cycle, which corresponds to the periodic configuration $[q, \overline{1000} \underline{0101} \underline{0101}]$.

Definition 16. *Prime Input Command Sequence*

Suppose $(q_1, a_1) \mapsto \dots \mapsto (q_n, a_n)$ is an execution sequence of input commands for (Q, A, η) . Then $(q_1, a_1) \mapsto \dots \mapsto (q_n, a_n)$ is a prime input command sequence if q_n is visited twice and all other states in this sequence are visited once. In other words, a prime input command sequence contains exactly one prime state cycle.

Lemma 2. *Prime Directed Edges \Leftrightarrow Prime Input Command Sequences*

Prime directed edges and prime input command sequences are in one-to-one correspondence.

Proof. (\Rightarrow) Let $\xi \Rightarrow \mathfrak{T}$ be a prime directed edge where $\xi = [q, v_0 v_1 \dots v_n, s]$ and $\mathfrak{T} = [r, w_0 w_1 \dots w_n, t]$. From the definition of a prime directed edge, over the next N computational steps some state r is visited twice, all other states in Q are visited at most once and there is a sequence of input commands $(q, v_s) \mapsto (q_1, a_1) \mapsto \dots \mapsto (r, a_k) \dots \mapsto (r, w_t)$ corresponding to these N steps. This is a prime input command sequence.

(\Leftarrow) Let $(q_1, a_1) \mapsto \dots \mapsto (r, a_{N+1})$ be a prime input command sequence with N computational steps. Then r is visited twice and all other states in the sequence are visited only once. Let $v_0 v_1 \dots v_n$ be the initial tape pattern over the window of execution during the N computational steps. Now $a_1 = v_s$ for some s . Let $w_0 w_1 \dots w_n$ be the final tape pattern over the window of execution as a result of these N steps. From the definition of the window of execution, the tape head is at some t satisfying $0 \leq t \leq n$ after these N steps. Thus, $[q, v_0 v_1 \dots v_n, s] \Rightarrow [r, w_0 w_1 \dots w_n, t]$ is a prime directed edge.

Lemma 3. *Any consecutive repeating state cycle is contained in a composition of one or more prime input command sequences.*

Proof. The proof is in the appendix of Nonlinear Dynamics and Synchronization 2012, available at www.springerlink.com.

Example 4.

This example illustrates the correspondence between prime directed edges and prime input command sequences for machine (Q, A, η) where $Q = \{2, 3, 4\}$, \mathcal{H} is the halting state, $A = \{0, 1\}$ and η is specified as $\eta(2, 0) = (3, 1, -1)$, $\eta(2, 1) = (4, 0, -1)$, $\eta(3, 0) = (4, 1, +1)$, $\eta(3, 1) = (4, 0, +1)$, $\eta(4, 0) = (\mathcal{H}, 0, 0)$, and $\eta(4, 1) = (2, 0, +1)$. The correspondence is shown below.

Prime Directed Edges	Prime Input Command Sequences
$[2, \underline{000}, 1] \Rightarrow [2, \underline{100}, 2]$	$(2, 0) \mapsto (3, 0) \mapsto (4, 1) \mapsto (2, 0)$
$[2, \underline{100}, 1] \Rightarrow [2, \underline{000}, 2]$	$(2, 0) \mapsto (3, 1) \mapsto (4, 1) \mapsto (2, 0)$
$[2, \underline{11}, 1] \Rightarrow [2, \underline{00}, 1]$	$(2, 1) \mapsto (4, 1) \mapsto (2, 0)$
$[2, \underline{001}, 1] \Rightarrow [2, \underline{101}, 2]$	$(2, 0) \mapsto (3, 0) \mapsto (4, 1) \mapsto (2, 1)$
$[2, \underline{101}, 1] \Rightarrow [2, \underline{001}, 2]$	$(2, 0) \mapsto (3, 1) \mapsto (4, 1) \mapsto (2, 1)$
$[3, \underline{010}, 0] \Rightarrow [3, \underline{101}, 1]$	$(3, 0) \mapsto (4, 1) \mapsto (2, 0) \mapsto (3, 0)$
$[3, \underline{110}, 0] \Rightarrow [3, \underline{001}, 1]$	$(3, 1) \mapsto (4, 1) \mapsto (2, 0) \mapsto (3, 0)$
$[4, \underline{10}, 0] \Rightarrow [4, \underline{11}, 1]$	$(4, 1) \mapsto (2, 0) \mapsto (3, 0) \mapsto (4, 1)$
$[4, \underline{11}, 0] \Rightarrow [4, \underline{00}, 1]$	$(4, 1) \mapsto (2, 1) \mapsto (4, 0)$

There are 9 distinct prime directed edges. Observe that $|Q|^2|A|^{|Q|+1} = 3^2 2^4 = 144$.

Definition 17. *Edge Sequence contains a consecutive repeating state cycle*

Lemma 2 implies that an edge sequence corresponds to a sequence of prime input commands. The expression *an edge sequence contains a consecutive repeating state cycle* means that the corresponding sequence of prime input commands contains a consecutive repeating state cycle.

Theorem 4. *Any consecutive repeating state cycle is contained in a prime directed edge sequence.*

Proof. This follows immediately from definitions 15, 17 and lemmas 2 and 3.

Procedure 1 *Searching for a consecutive repeating state cycle in a prime directed edge sequence*

Given an edge sequence whose corresponding prime input command sequence $(q_0, a_0) \mapsto (q_1, a_1) \mapsto \dots \mapsto (q_N, a_N)$ has length N .

Set $n = \frac{N}{2}$ if N is even; otherwise, set $n = \frac{N+1}{2}$ if N is odd.

For each k in $\{0, 1, 2, \dots, n-1\}$

For each j in $\{0, 1, \dots, N - 2k - 1\}$

{
 If $(q_j, a_j) \mapsto \dots \mapsto (q_{j+k}, a_{j+k})$ equals $(q_{j+k+1}, a_{j+k+1}) \mapsto \dots \mapsto (q_{j+2k+1}, a_{j+2k+1})$
 return consecutive repeating state cycle $(q_j, a_j) \mapsto \dots (q_{j+k}, a_{j+k}) \dots (q_{j+2k+1}, a_{j+2k+1})$
 }
 }

If the outer for loop is exited without finding a consecutive repeating state cycle
 return NO consecutive repeating state cycles were found.

Procedure 2 *Prime Directed Edge Search Procedure*

Read Turing Machine (Q, A, η) as input.

Set $\mathfrak{P} = \emptyset$.

For each non-halting state q in Q

For each pattern $a_{-|Q|} \dots a_{-2} a_{-1} a_0 a_1 a_2 \dots a_{|Q|}$ selected from $A^{2|Q|+1}$

{
 Square $-|Q| \dots -1 \ 0 \ 1 \ \dots \ |Q|$
 Contents $a_{-|Q|} \dots a_{-1} \ \underline{a_0} \ a_1 \ \dots \ a_{|Q|}$

1. In start state q , $T(k) = a_k$ where $-|Q| \leq k \leq |Q|$, and tape head location 0, execute (Q, A, η) until one state is visited twice or a halting state is reached. The execution takes $\leq |Q|$ steps.

2. If execution does not halt, set r equal to the state that is first visited twice.

3. Over this window of execution, construct a prime directed edge $\mathfrak{H} \Rightarrow \mathfrak{T}$ where
 $\mathfrak{H} = [q, v_0 v_1 \dots v_n, s]$, $\mathfrak{T} = [r, w_0 w_1 \dots w_n, t]$ and $0 \leq s, t \leq n \leq |Q|$.

4. Set $\mathfrak{P} = \mathfrak{P} \cup \{\mathfrak{H} \Rightarrow \mathfrak{T}\}$.

}

Remark 3. Prime Directed Edge Search Procedure finds all edges

Procedure 2 finds all prime directed edges of (Q, A, η) and all halting nodes.

Proof. Let $\mathfrak{H} \Rightarrow \mathfrak{T}$ be a prime directed edge of (Q, A, η) . Then $\mathfrak{H} \Rightarrow \mathfrak{T}$ has a head node $\mathfrak{H} = [q, v_0 v_1 \dots v_n, s]$, for some state q in Q , for some tape pattern $v_0 v_1 \dots v_n$ that lies in A^{n+1} , such that $n \leq |Q|$ and $0 \leq s \leq n$. In the outer loop of procedure 2, when q is selected from Q and in the inner loop when the tape pattern $a_{-|Q|} \dots a_{-2} a_{-1} a_0 a_1 a_2 \dots a_{|Q|}$ is selected from $A^{2|Q|+1}$ such that $a_{-s} = v_0 \dots a_{-k} = v_{s-k} \dots a_0 = v_s \dots a_k = v_{s+k} \dots a_{n-s} = v_n$ then the machine execution in procedure 2 will construct prime directed edge $\mathfrak{H} \Rightarrow \mathfrak{T}$.

When the head node is a halting node, the machine execution must halt in at most $|Q|$ steps. Otherwise, it would visit a non-halting state twice and be a non-halting head node. The rest of the argument for this halting node is the same as for the non-halting head node.

To avoid subscripts of a subscript, let p_j and the subscript $p(j)$ represent the same number. $\mathfrak{P} = \{\mathfrak{H}_1 \Rightarrow \mathfrak{T}_1, \dots, \mathfrak{H}_k \Rightarrow \mathfrak{T}_k, \dots, \mathfrak{H}_N \Rightarrow \mathfrak{T}_N\}$ is the set of all prime directed edges. $E([p_1], 1)$ is the edge sequence $[(\mathfrak{H}_{p(1)} \Rightarrow \mathfrak{T}_{p(1)}, \mathfrak{N}_{p(1)})]$ of length 1

where $\mathfrak{N}_{p(1)} = \mathfrak{T}_{p(1)}$ and $1 \leq p_1 \leq |\mathfrak{P}|$. Next $E([p_1, p_2], 2)$ is the edge sequence $[(\mathfrak{H}_{p(1)} \Rightarrow \mathfrak{T}_{p(1)}, \mathfrak{N}_{p(1)}), (\mathfrak{H}_{p(2)} \Rightarrow \mathfrak{T}_{p(2)}, \mathfrak{N}_{p(2)})]$ such that $1 \leq p_1, p_2 \leq |\mathfrak{P}|$ and $\mathfrak{N}_{p(2)} = \mathfrak{N}_{p(1)} \oplus (\mathfrak{H}_{p(2)} \Rightarrow \mathfrak{T}_{p(2)})$. In general, $E([p_1, p_2, \dots, p_k], k)$ denotes the edge sequence of length k which is $[(\mathfrak{H}_{p(1)} \Rightarrow \mathfrak{T}_{p(1)}, \mathfrak{N}_{p(1)}), (\mathfrak{H}_{p(2)} \Rightarrow \mathfrak{T}_{p(2)}, \mathfrak{N}_{p(2)}), \dots, (\mathfrak{H}_{p(k)} \Rightarrow \mathfrak{T}_{p(k)}, \mathfrak{N}_{p(k)})]$ where $\mathfrak{N}_{p(j+1)} = \mathfrak{N}_{p(j)} \oplus (\mathfrak{H}_{p(j+1)} \Rightarrow \mathfrak{T}_{p(j+1)})$ for each j satisfying $1 \leq j \leq k-1$ and $1 \leq p(j) \leq |\mathfrak{P}|$.

Procedure 3 *Immortal Periodic Point Search Procedure*

Read Turing Machine (Q, A, η) as input.

Use procedure 2 to find all prime directed edges \mathfrak{P} .

Set $k = 1$. Set $\mathfrak{E}(1) = \{E([1], 1), E([2], 1), \dots, E([|\mathfrak{P}|], 1)\}$.

While ($\mathfrak{E}(k) \neq \emptyset$)

{

 Set $\mathfrak{E}(k+1) = \emptyset$.

 For each $E([p_1, p_2, \dots, p_k], k)$ in $\mathfrak{E}(k)$

 For each prime directed edge $\mathfrak{H}_j \Rightarrow \mathfrak{T}_j$ in \mathfrak{P}

 {

 if $\mathfrak{H}_j \Rightarrow \mathfrak{T}_j$ link matches with $\mathfrak{N}_{p(k)}$ then

 {

 Set $p_{k+1} = j$.

 Set $\mathfrak{E}(k+1) = \mathfrak{E}(k+1) \cup E([p_1, p_2, \dots, p_k, p_{k+1}], k+1)$.

 If $E([p_1, p_2, \dots, p_k, p_{k+1}], k+1)$ has a consecutive repeating state cycle then return the consecutive repeating state cycle and exit the while loop.

 }

 }

 }

 }

 }

k is incremented.

}

If the while loop exits because $\mathfrak{E}(m) = \emptyset$ for some m , then return \emptyset ; in other words, (Q, A, η) has only halting configurations.

Remark 4. $|\mathfrak{E}(k)| \leq |\mathfrak{P}|^k$

Definition 18. *Periodic Turing Machine*

A Turing machine (Q, A, η) that has at least one periodic configuration, whenever it has an immortal configuration is said to be a *periodic* Turing machine.

Remark 5. If $E([p_1, p_2, \dots, p_r], r)$ contains a consecutive repeating state cycle, then the corresponding periodic point has period $\leq \frac{1}{2} \sum_{k=1}^r |\mathfrak{H}_{p(k)} \Rightarrow \mathfrak{T}_{p(k)}|$.

Proof. Theorem 2 implies that a consecutive repeating state cycle determines an immortal periodic point. The length of the state cycle equals the period of the periodic point. Further, the number of input commands corresponding to the number of computational steps equals $|\mathfrak{H}_{p(k)} \Rightarrow \mathfrak{T}_{p(k)}|$ in directed edge $\mathfrak{H}_{p(k)} \Rightarrow \mathfrak{T}_{p(k)}$.

Theorem 5. *When machine (Q, A, η) is periodic, procedure 3 terminates in a finite number of steps with either a consecutive repeating state cycle or for some positive integer J , then $\mathfrak{E}(J) = \emptyset$, which means all of the configurations of (Q, A, η) are halting.*

Proof. If (Q, A, η) has at least one configuration (q, k, T) that is an immortal, then by definition 18, this implies the existence of a periodic point p with some finite period N . Thus, from Theorem 1, there is a consecutive repeating state cycle that corresponds to the immortal periodic point p . Since procedure 3 searches through all possible prime edge sequences of length k , a consecutive repeating state cycle will be found that is contained in a prime directed edge sequence with length at most $2N$. Thus, periodic point p of period N will be reached before or while computing $\mathfrak{E}(2N)$.

Otherwise, (Q, A, η) does not have any immortal configurations; in other words, for every configuration, (Q, A, η) halts in a finite number of steps. Claim: There is a positive integer J such that every edge sequence terminates while executing procedure 3. By reductio absurdum, suppose not. Then there is at least one infinite prime directed edge sequence that exists. This infinite edge sequence corresponds to an immortal configuration, which contradicts that (Q, A, η) is a periodic machine.

Example 5. A Turing Machine with only aperiodic immortal configurations

This example is based on work in [2]. The state set $Q = \{a, b, c, d, e, f\}$ and the alphabet set $A = \{0, 1, 2, 3\}$. The halting state is \mathcal{H} . In the following table, the Turing program is presented as quintuples (q, a, r, b, m) where $\eta(q, a) = (r, b, m)$.

$(a, 0, d, 1, +1)$	$(a, 1, f, 1, +1)$	$(a, 2, f, 2, +1)$	$(a, 3, f, 3, +1)$
$(b, 0, c, 1, -1)$	$(b, 1, e, 1, -1)$	$(b, 2, e, 2, -1)$	$(b, 3, e, 3, -1)$
$(c, 0, a, 2, -1)$	$(c, 1, f, 1, +1)$	$(c, 2, f, 2, +1)$	$(c, 3, f, 3, +1)$
$(d, 0, b, 2, +1)$	$(d, 1, e, 1, -1)$	$(d, 2, e, 2, -1)$	$(d, 3, e, 3, -1)$
$(e, 0, a, 3, -1)$	$(e, 1, a, 0, -1)$	$(e, 2, d, 0, +1)$	$(e, 3, f, 0, +1)$
$(f, 0, b, 3, +1)$	$(f, 1, b, 0, +1)$	$(f, 2, c, 0, -1)$	$(f, 3, e, 0, -1)$

Observe that any periodic tape pattern with any non-halting state is immortal. However, none of these configurations are periodic because none are returned to in a finite number of execution steps.

Remark 6. Procedure 3 does not halt on aperiodic Turing machines.

6 Discussion and Further Work

In [12], Turing presented the Halting problem and proved that the Halting problem is undecidable with a Turing Machine. In [8], Hooper proved that the Turing Immortality problem is undecidable. Both papers assume that every initial machine configuration is M -bounded for some finite M (i.e., the tape is bounded by blank symbols

before the Turing machine program begins executing). In [1], Berger demonstrated an aperiodic tiling that proved that the tiling problem was undecidable. In light of [2] and the results presented here, the aperiodicity appears to be an integral part of the undecidability.

Procedure 2 finds all the prime directed edges and works for any Turing machine. Furthermore, the construction of the edge sequences via link matching inside Procedure 3 works on any Turing machine; and at the k th pass through the outer loop, this construction explores all possible immortal configurations up to an edge sequence length of k prime directed edges. The limitation of procedure 3 is on the aperiodic Turing machines and is due to the exit condition of finding a consecutive repeating state cycle.

Although the consecutive repeating state cycle characterizes any periodic configuration in the Turing machine, a broader notion of recurrence is needed to address the more complex behavior of aperiodic immortal configurations that are initially M -bounded. Lemma 1 implies that every immortal configuration is contained by a unique prime directed edge sequence, so prime directed edge sequences cover all possible Turing program behaviors. Research that further develops the mathematical notions described here could help better understand the aperiodic immortal configurations, aperiodic Turing machines and perhaps undecidability.

8 Acknowledgement

I would like to thank Tony Lauck, Michael Jones, Kyandoghene Kyamakya, Don Saari and Sandy Zabell for their helpful advice and discussions. I would like to thank Lutz Mueller for creating newLISP, which has been extremely useful in my research.
